

# Operating Systems

## 08. Real-Time Scheduling

Paul Krzyzanowski

Rutgers University

Spring 2014

# What's wrong with priorities?

---

- Fixed priorities:
  - Should I be #4? ... #6? ... #15?
- Dynamic priorities
  - I have no idea what my priority is because the CPU changes it!

# Real-time demands

- We don't always need a LOT of CPU time but we may need it at the right intervals
  - E.g., decode 30 frames per second of video
- We might have tight deadlines
  - E.g., complete task within the next 500 ms
- Conventional process scheduling algorithms focused on fairness, compromise, and providing the best overall experience

# Deadlines in real-time systems

- Start time (**release time**)
  - E.g., response to a sensor: start within 20 ms from sense time
- Stop time (**deadline**)
  - Scheduler must allot enough CPU time to complete
- **Hard deadline**
  - There is no value to the computation if it completes after the deadline
  - **Safety critical system**: critical start time and deadline
- **Soft deadline**
  - The value of a late result diminishes with time

# Process types

- **Terminating process**
  - Runs and exits (e.g., service a sensor event)
  - How much time does it take to run to completion?
  - Deadline = time to finish
- **Nonterminating process**
  - Interested in time between events
    - E.g., fill a 4 KB audio buffer every 500 ms
    - E.g., decode a video frame every 67 ms
  - Compute time = time to compute periodic event
  - Deadline = time to have periodic results ready

# How much can we do?

- Don't expect magic
- E.g.,
  - decoding 1 video frame takes 20 ms
  - we want to decode 2 video frames at 30 frames/sec
  - *We'll fail*:  $2 \times 30 \times 20 = 1200 \text{ ms} > 1000 \text{ ms}$  (1 sec = 1000 ms)
- If  $T$  = period,  $D$  = deadline,  $C$  = compute time:

$$C \leq D \leq T$$

# Earliest Deadline Scheduling

- Each process tells OS its time deadline
- Scheduler picks the process in closest to its deadline
  - Usually one process runs to completion if it has an earlier deadline
  - Will be preempted if a process with an even earlier deadline starts

# Least Slack Scheduling

- Consider **remaining time** and **deadline**
- Look not only at the deadline but how much we can procrastinate

$$\text{slack} = (\text{time to deadline}) - (\text{amount of computation})$$

- E.g., suppose

$$C \text{ (compute time)} = 5 \text{ ms}$$

$$D \text{ (deadline)} = 20 \text{ ms from now}$$

$$\text{slack} = D - C = 15 \text{ ms}$$

# Least Slack vs. Earliest Deadline First

## Earliest Deadline First

- We always work on the earliest deadline process and delay others

## Least Slack

- Get a balanced result in that we keep the differences to deadlines balanced

If there's not enough time for everything:

- **EDF**: may hit only the early deadlines
- **LS**: all deadlines may be missed but roughly by the same amount

# Rate monotonic analysis

- Method of assigning static priorities to periodic processes
- Works with a static priority scheduler
- Must know all real-time processes running at the same time and their period
- Rate monotonic priority assignment is optimal
  - If the it is possible for all deadlines to be met then they will be met with rate monotonic assignment

# Assigning priorities

- Highest frequency (smallest period) process gets the highest priority
- Successively lower frequency processes get lower priorities
- Scheduling is via a simple priority scheduler
- If two processes have the same priority, they can round-robin

# Rate monotonic example

- Process A runs every 50 ms for 20 ms
- Process B runs every 50 ms for 10 ms
- Process C runs every 30 ms for 10 ms

Rate monotonic analysis:  
Schedule C first, then A or B

No rate monotonic  
priority assignment:  
C misses a period!

# The End
